## NEW QUESTION: 2

You are developing a C# application. The application includes a class named Rate. The following code segment implements the Rate class:

You define a collection of rates named rateCollection by using the following code segment:

```
Collection<Rate> rateCollection = new  
Collection<Rate>();
```

The application receives an XML file that contains rate information in the following format:

You need to parse the XML file and populate the rateCollection collection with Rate objects.

How should you complete the relevant code? (To answer, drag the appropriate code segments to the correct locations in the answer area. Each code segment may be used once, more than once, or not at all. You may need to drag the split bar between panes or scroll to view content.)

**Answer:**

Explanation:

Explanation

Explanation

\* Target 1: The element name is rate not Ratesheet.

The Xmlreader readToFollowing reads until the named element is found.

\* Target 2:

The following example gets the value of the first attribute.

```
reader.ReadToFollowing("book");
```

```
reader.MoveToFirstAttribute();
```

```
string genre = reader.Value;
```

```
Console.WriteLine("The genre value: " + genre);
```

\* Target 3, Target 4:

The following example displays all attributes on the current node.

```
C#VB
```

```
if (reader.HasAttributes) {
```

```
Console.WriteLine("Attributes of &lt;" + reader.Name + "&gt;");
```

```
while (reader.MoveToNextAttribute()) {
```

```
Console.WriteLine(" {0}={1}", reader.Name, reader.Value);
```

```
}
```

```
// Move the reader back to the element node.
```

```
reader.MoveToElement();
```

```
}
```

The XmlReader.MoveToElement method moves to the element that contains the current attribute node.
